Silver nanoparticle  
Silver hydroxyapatite composite  
*Uncaria gambir* Roxb.  
Bone implant

## ABSTRACT

A well-distributed nano-silver hydroxyapatite composite has been successfully prepared by a one-pot synthesis method. Hydroxyapatite was separately synthesized by a sol-gel method, then impregnated with silver nanoparticles with the mediation of *Uncaria gambir* Roxb. leaf extract in the presence of three kinds of alkanolamine compound; monoethanolamine (MEA), diethanolamine (DEA), and triethanolamine (TEA) as capping agents. The effect of different capping agents on the properties of the silver nanoparticles and the nano-silver hydroxyapatite composite were studied. UV–visible spectrophotometer analysis exhibited absorbance peaks at 402–439 nm which specifically corresponds to spherical silver nanoparticles. Higher optical absorbance was observed in TEA-capped silver nanoparticles, than in DEA and MEA-capped ones. X-ray diffraction (XRD) analysis showed a highly crystalline hexagonal structure for hydroxyapatite and no detected metallic silver. However, the presence of 1.65% silver was confirmed by energy dispersive x-ray (EDX) spectroscopy analysis. Transmission electron microscopy (TEM) analysis revealed spherical silver nanoparticles with a size range of 2–62 nm (smallest mean diameter of 2 nm) adhered to the hydroxyapatite surface. The TEA capped impregnated silver nanoparticles were the smallest, corresponding to the best capping performance, followed by those capped by DEA and MEA. Small-sized nanoparticles on hydroxyapatite are beneficial for highly antibacterial bone implants.

## 1. Introduction

In recent decades, the study of calcium orthophosphate based inorganic biomaterials has been of increasing interest due to their wide applications in the field of health and medicine [1–3]. One of the most studied of these is hydroxyapatite (HA) (chemical formula  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ ) which is used as a graft material for bone and for tooth substitution and repair due to its biocompatibility, bioactivity, and osteoconductivity [4,5]. Synthesis of hydroxyapatite has been achieved using a hydrothermal method [6], a microwave-assisted method [1], sol-gel [2], and a precipitation method [5]. The sol-gel method is considered efficient, easy, and environmentally friendly as it is low-cost, requires a low formation temperature and yet achieves high degrees of homogeneity and purity [7].

However, one of the main problems of this material is infections that can occur after bone implantation or other surgical operations since these biomaterials provide sites for potential bacteria adhesion. This process might be due to the absorption of protein, amino acid, and

any other organic compounds into HA [8]. Furthermore, antibiotics loaded into implant material tend to be rapidly flushed out by body fluid resulting in long term post-surgical infections [9]. This situation is made worse by the increase of multi-drug resistant (MDR) bacteria. Therefore, there is a demand for the development of a new generation of modified antibacterial agents to solve this problem [10,11]. Nanotechnology offers a promising approach to the fabrication of antibacterial agents in the form of metallic nanoparticles. In recent years, silver nanoparticles with their antibacterial properties have gained a lot of attention due to their potential applications in the biomedical field [12,13]. It could be expected that the incorporation of silver nanoparticles into hydroxyapatite could help avoid post-operative inflammation and bacterial infection [14]. In addition, compared to bulk materials, silver nanoparticles have excellent properties due to the high surface area to volume ratio which results in a beneficial effect at low concentrations when incorporated into a biomaterial. This point is crucial for the health of the patient as it minimizes the amount of this metal in the body [15].

In our previous studies, stable colloidal silver nanoparticles have been successfully synthesized by bio-reducing  $\text{Ag}^+$  using *Uncaria gambir* Roxb. as a reducing agent in presence of MEA [16] and DEA [17] as a capping agent. *Uncaria gambir* Roxb. is one of commodity in West Sumatera, Indonesia and for long time had been used as traditional medicine due to the content of some polyphenol compounds predominantly catechin. Those polyphenol compound is expected to reduce  $\text{Ag}^+$  to  $\text{Ag}^0$ . The formation of those stable and small-sized colloidal silver nanoparticles was conducted using a simple method and did not require the use of expensive technological equipment. Modifying this method of silver nanoparticle fabrication by the addition of a capping agent should result in control over their size and stability which would be advantageous since the antibacterial activity of metallic nanoparticles is strongly influenced by size [18]. Hence, in this study, three kinds of alkanolamine compound, i.e. MEA, DEA, and TEA were trialled as capping agents in the preparation of silver nanoparticles using *Uncaria gambir* Roxb. leaf extract using 1 pot synthesis with hydroxyapatite powder. The effect of alkanolamine compound structure on the properties of silver nanoparticles was studied and the effect of each capping agent were compared using UV–Vis spectrophotometry, XRD, EDX, and TEM analysis.

## 2. Experimental procedures

### 2.1. Synthesis of hydroxyapatite

Hydroxyapatite was separately synthesized using a sol-gel method based on previous report by Jamarun et al. [7]. The calcium precursor used in the reaction was extracted from cockle shells (*Anadara granosa*) as in Azis et al. (2015) [6]. The cockle shells were cleaned, washed, dried, and ground to a coarse powder. They were then calcined at 900 °C for 5 h to obtain CaO.  $(\text{NH}_4)_2\text{HPO}_4$  (Merck, analytical grade) was used as a phosphor precursor.

This CaO was diluted into  $\text{HNO}_3$  2 M (Merck, analytical grade) and then stirred at a constant rate of 600 rpm at 85 °C for 20 min 250 ml  $(\text{NH}_4)_2\text{HPO}_4$  was added drop-wise to the solution while stirring at 110 °C and pH adjusted to 11 using  $\text{NH}_4\text{OH}$  (Merck, Analytical grade). The mixture was stirred for 5 h to obtain white sol. After 24 h of aging, the gel was filtered and dried in a 110 °C oven for 6 h to obtain a powder. This was then calcined at 900 °C for 5 h resulting in hydroxyapatite.

### 2.2. Synthesis of HAp-AgNps composite

*Uncaria gambir* Roxb. leaves were taken from the experimental garden, Andalas University, Padang, Indonesia and extracted using the method of Labanni et al. [16]. Fresh leaves were washed, dehydrated by shade drying, and mashed up to obtain powder. Extraction was conducted using water solvent and stirring at a constant rate at 65 °C for 2 h then filtered. This filtrate was then stored in a sealed bottle at 4 °C.

Nano-silver hydroxyapatite composite was fabricated by precipitation method. 1 mM silver nitrate (Merck, Analytical grade), 2 mM of the chosen alkanolamine (Merck, Analytical grade), and 4% leaf extract with as-synthesized hydroxyapatite to make a total volume of 50 mL were stirred together in a dark environment in 1 pot for 24 h at a constant rate of 600 rpm at room temperature. After stirring, the mixture was filtered and the residue was washed using distilled water, then dried in a hot air oven to produce powder. The synthesized nano-silver hydroxyapatite composite fabricated using MEA, DEA, or TEA as a capping agent are hereafter denoted as HAp-AgNps MEA, HAp-AgNps DEA, and HAp-AgNps TEA, respectively. In addition, the synthesis of HAp-AgNps without the use of a capping agent was also carried out as control, which is hereafter denoted as HAp-AgNps0.

## 2.3. Characterization

The UV–Vis Spectrophotometry analysis of silver nanoparticles was carried out using Thermo Scientific Evolution 201 UV–Vis in wavelength range of 200–800 nm. The crystal structure of synthesized HAp-AgNps was investigated using X-Ray Diffraction Rigaku Ultima IV with  $\text{CuK}\alpha$  radiation with a scanning rate of  $2^\circ \text{min}^{-1}$  at 60 kV and 20 mA. The size and the morphology of HAp-AgNps were evaluated using JEOL JEM 2100. Chemical composition of the samples was determined using EDX JEOL JED 2300.

## 3. Results and discussion

### 3.1. UV–Vis Spectrophotometry analysis

The formation of silver nanoparticles was indicated by a colour change from colourless to yellowish-brown 5 min after the reaction. The presence of the particles was then tested by UV–Vis spectrophotometry analysis over the wavelength range of 200–800 nm (Fig. 1). Optical absorption peaks occurring at 402–439 nm were observed in all four samples. The absorbance value increased with the presence of alkanolamine in the reaction which suggested that, besides acting as a capping agent as expected, these alkanolamine compounds acted as reducing agents as well. AgNps-TEA provided the highest absorbance value followed by AgNps-DEA, then AgNps-MEA. This result suggested that the structure of alkanolamine compounds used significantly affects the number of silver nanoparticles formed in the reaction. This might be due to the number of hydroxyl groups in the structure, which have a role in reducing silver cations to metallic silver. Furthermore, the use of different alkanolamine compounds also resulted in different wavelength ranges in the absorbance spectrum, with AgNps-TEA absorbing at shorter wavelength than AgNps-DEA and AgNps-MEA. The Mie theory of scattering for spherical metal nanoparticles indicates that a shift to longer wavelength corresponds to a larger particle size [19]. Hence, this result suggests that the use of TEA resulted in smaller sized nanoparticles than those of DEA and MEA capped reactions. AgNps-TEA capped nanoparticles also had a narrower absorbance peak suggesting a narrower size range. This result was subsequently affirmed by TEM analysis.

### 3.2. X-ray diffraction analysis

The result of XRD analysis of the HAp-AgNps powder synthesized with each alkanolamine compound is displayed in Fig. 2. The diffraction pattern of HAp-AgNps in all samples showed peaks at  $2\theta$  values of 26.10, 32.00, 32.43, 33.16, 46.86, and 49.62° indicating a well-

Fig. 1. UV–Vis absorption spectrum of *Uncaria gambir* Roxb. mediated silver nanoparticle with alkanolamine compounds as capping agent.

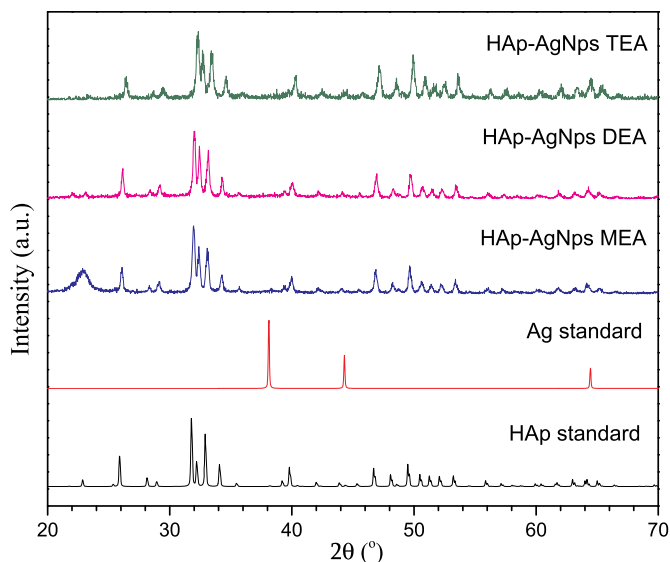

Fig. 2. XRD pattern of synthesized HAp-AgNps.

Fig. 3. XRD pattern fitted with Le Bail method for bi-phasic HAp-AgNps.

crystallized hexagonal structured hydroxyapatite based on the ICSD #26204 standard. This result indicated that hydroxyapatite had been successfully synthesized using *Anadara granosa* as a calcium precursor using sol-gel method. The metallic silver was not evident in the diffraction pattern of the HAp-AgNps samples. Similar results have also been found in previous researches about HAp-AgNps composite, where metallic silver was not detected in XRD analysis [20,21]. In fact, the percentage of silver nanoparticles was very small compared to hydroxyapatite in the samples and this could be the reason for the lack of observable metallic silver peaks.

In order to display the metallic silver peak in XRD analysis more clearly, Le Bail refinement was conducted on one of the samples using Rietica software using 2 phase standards of hydroxyapatite and silver. The plot is shown in Fig. 3, where the black circles represent the experimental XRD data, the red line represents calculated data of both hexagonal hydroxyapatite and face-centred cubic silver phases, and the green line represents the difference pattern. The result shows the presence of Ag at 2θ of 38.20 and 44.21°, marked by an asterisk (\*), in accordance with the ICSD #604631 standard for metallic silver. The Rp value was found to be 16.09 with a goodness of fit ( $\chi^2$ ) of 2.169 which is an acceptable value according to the basic principles of goodness of fit [22]. In comparison to this result, the Rp value of single-phase hydroxyapatite refinement was found to be 16.72. The decrease of the Rp value in two-phase refinement indicates the presence of the Ag peak in the diffraction pattern.

### 3.3. Energy dispersive X-Ray analysis

Elemental analysis using EDX further confirmed the presence of Ag in the samples. Fig. 4 showed the elemental analysis result of HAp-AgNps TEA with an Ag peak at approximately 3 keV, with a mass percentage of 1.68%. This clearly confirmed the presence of silver in the samples as indicated in the XRD analysis. Not surprisingly, Ca and P were also evident in the sample from the content of the hydroxyapatite.

### 3.4. Transmission electron microscopy analysis

The presence of nanometer-sized silver was clearly observed in the TEM. Spherical nanoparticles with size range of 2–15 nm could be clearly observed attached on the surface of micrometer-sized hydroxyapatite (Fig. 5). The very small size and ratio of silver nanoparticle compared to hydroxyapatite is a strong reason for the absence of metallic silver peaks in the XRD analysis result. A highly significant difference was observed between the appearance of the capped HAp-

Fig. 4. EDX analysis of HAp-AgNps TEA.

Fig. 5. TEM Images of a) HAp-AgNps MEA, b) HAp-AgNps DEA, c) HAp-AgNps TEA, and d) HAp-AgNps0.

AgNps and AgNps0. Silver nanoparticles on HAp-AgNps0 (Fig. 5d) tended to be stacked and agglomerated in certain sites, while in HAp AgNps-MEA, HAp-AgNps DEA, and HAp-AgNps TEA (Fig. 5a, b, c) silver nanoparticles were well distributed over the HAp surface. A similar

result has been previously reported by Nirmala et al. [23] who synthesized HAp-AgNps from bovine femur bone where hydroxyapatite was presented as microstructure with silver nanoparticles attached on the periphery. The present results clearly suggest that the use of

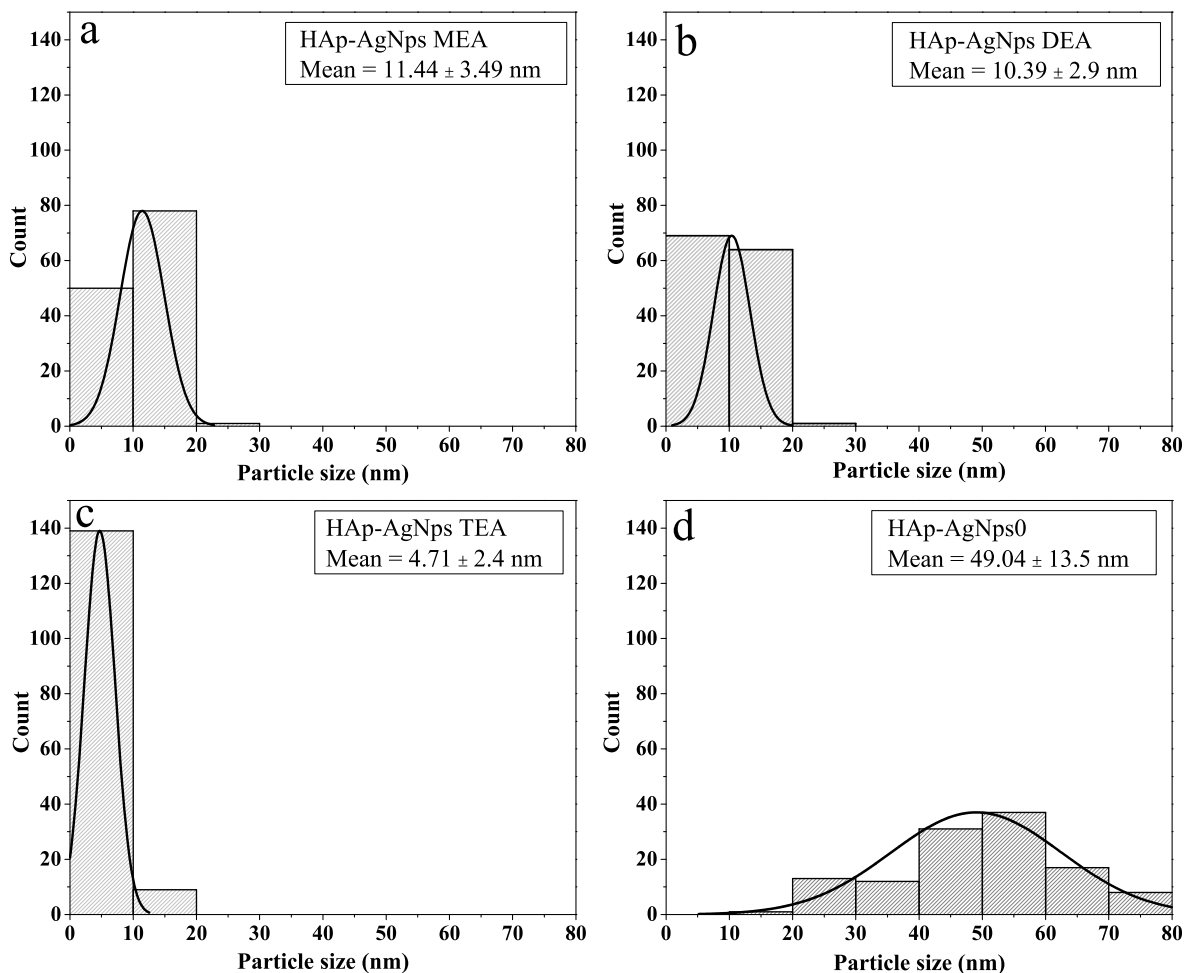

Fig. 6. Particle size distribution of AgNps on a) HAp-AgNps MEA, b) HAp-AgNps DEA, c) HAp-AgNps TEA, and d) HAp-AgNps0.

alkanolamine compounds strongly affects the distribution of AgNps on the HAp surface. The attachment of silver nanoparticles on the surface of an implant is more advantageous for antibacterial activity than silver nanoparticles attached inside the implant [24].

Fig. 6 shows particle size distribution of as-synthesized HAp-AgNps as determined by ImageJ software. It was discovered that the mean diameter of nano-silver in HAp-AgNps0 was 49 nm, 10 times larger than that of nano-silver in HAp-AgNps TEA. In addition, nano-silver in HAp-AgNps0 (Fig. 6d) showed a much broader particle size range than those in the alkanolamine capped samples indicating that the use of capping agents was indeed able to control growth and affect the size uniformity of nanoparticles.

In addition, there was a correlation between the type of capping agent used (MEA, DEA, and TEA) and the size of silver nanoparticles. Nano-silver in HAp-AgNps TEA provided the smallest particle size, followed by nano-silver in HAp-AgNps DEA, then HAp-AgNps MEA. As TEA has more hydroxyl groups than DEA and MEA has even fewer, it is concluded that the higher number of hydroxyl groups in the structure results in the smaller mean size. Several studies have reported that in the stabilizing mechanism of silver nanoparticles by alkanolamine compounds, an electrostatic interaction occurs between free electron pairs from nitrogen and positively charged AgNps, resulting in a protective monolayer. This monolayer then caps nanoparticles to avoid excessive fusion, hence controls the growth and size of nanoparticles [16,25,26]. It is assumed that hydroxyl groups of alkanolamine compound obstruct further interaction among silver nanoparticles. The higher number of hydroxyl groups in TEA could be the reason for the optimum capping performance of TEA, thus resulting in the smallest nanoparticle size seen in the TEM as well as the wavelength shift in the UV-Vis spectrophotometry analysis. These silver nanoparticles are of a much smaller size than those previously reported by Bharti et al. who used trisodium citrate as a reducing agent, resulting in nano-silver with mean particle size of 58.38 nm [27].

#### 4. Conclusion

A well-distributed nano-silver hydroxyapatite composite has been successfully synthesized using a 1 pot green synthesis method with *Uncaria gambir* Roxb. leaf extract as the bio-reducing agent and each of three different alkanolamine compounds as capping agents. UV-Vis spectrophotometry and EDX analysis confirmed the formation of silver nanoparticles. XRD analysis showed the formation of a highly crystalline hexagonal structured hydroxyapatite. TEM analysis confirmed the presence of spherical silver nanoparticles with a diameter range of 2–62 nm adhering to the hydroxyapatite surface. The results suggested that alkanolamine compounds can play a crucial role in fabricating stable and well-distributed silver nanoparticles on the hydroxyapatite surface. HAp-AgNps TEA showed smaller AgNps than those of MEA and DEA. This small size indicates that although the amount of silver contained in the hydroxyapatite compound was extremely small, the silver's surface distribution should have a significant antibacterial impact. Silver nanoparticles incorporated hydroxyapatite using *Uncaria gambir* Roxb. leaf extract and TEA could produce materials highly suitable for biomedical applications.
