Research Article Effects of the Substitution of Corn with Sorghum and the Addition of Indigofera Leaf Flour on the Performance of Laying Hens Riesi Sriagtula, Ade Djulardi, Ahadiyah Yuniza, Wizna\*, <u>Zurmiati Department of Animal Feed and Technology</u>, Faculty of Animal Science, Andalas University,

Padang 25163,Indo- nesia. Abstract| Sorghum (Sorghum bicolorL. Moench) is an alternative feed ingredient that is often used to replace corn

in poultry feed, especially in the tropics. <u>This study aims to</u> evaluate <u>the</u>

substitution of corn with sorghum, with the addition of Indigofera

leaf flour, <u>on the performance of laying hens.</u> A <u>completely randomized</u>

study <u>design was used in this</u> research <u>with</u> four <u>treatments</u>:

A. 26% commercial concentrate + 40% corn + 0% sorghum + 0% Indigofera; B. 23% commercial concentrate + 20% corn + 20% sorghum + 4% Indigofera; C. 22% commercial concentrate + 10% corn + 30% sorghum + 5% Indigofera; and D. 21% commercial concentrate + 0% corn + 40% sorghum + 6% Indigo- fera. Each treatment was repeated fivetimes. All the bird received Waretha probiotic in drinking water at a dose of 43x1012 CFU/mL. Feed consumption, egg mass, feed conversion, hen-day

production, <u>and egg weight</u> were measured. <u>The results showed that</u>

<u>the</u> substitution <u>of</u> corn with sorghum with the addition of Indigofera leaf flour did not pro- duce <u>significant differences (P>0.05) in feed</u> <u>consumption</u>, egg period, feed conversion, hen-day production, and egg weight. In conclusion, the substitution of corn with 40% sorghum with the addition of 6% Indigofera leaf flour and the provision of Waretha probiotics in each treatment with doses as high as 43x1012 CFU/mL did not interfere with the performance of laying hens. properly cited. INTRODUCTION L aying hen farms have been very dependent on imports of cereal feed ingredients as a source of protein and energy, including corn kernels. The structure of animal produce better nutritional production yields per area and sorghum prices are lower than that of corn (Legiro et al., 2009). Sorghum plants can produce seeds reaching 3-6 tons/ha (Suprivanto, 2015), while the national average corn production is still low at approximately 4.23 tons/ha feed production costs is dominated by raw materials in (Swastika et al., 2011). In terms of nutritional composi- the form of corn which comprises 51.4% of the costs. The tion, sorghum contains metabolic energy; however, the di- problem of price and availability of corn as outlined above gestibility of sorghum is 5% lower than corn, but sorghum has encouraged much research on alternative feed ingredi- has a higher crude protein content (NRC, 1994). Another ents for poultry feed. The efforts to replace corn with other consideration of including sorghum in laying rations is the grains have not been successful, so corn remains the main presence of tannins. Sorghum contains antinutrient com- raw material for feed in the world (Kasryno et al., 2008). pounds, such as tannins and phytic acid (Suarni and Sing- Among alternative ingredients are sorghum (Sorghum bi- gih, 2002). color L. Moench), which presents adequate

<u>nutritional characteristics and is often used to replace corn</u>, especially Tannins can form carbohydrates and complex proteins to <u>in semi-arid</u>

regions <u>and</u>	the tropics where sorghum	plants reduce
digestibility and	ration <u>palatability (Rostagno et</u>	al., 2005). However,
the development of	low tannin sorghum varieties has	made it possible

to increase the percentage of sorghum contained in non-Ruminant animal rations, in- cluding that ratio present in the feed of laying hens (More- no et al., 2007). Sorghum plantshave the specialized ability to grow back after being cut or harvested called ratoon. Ra- toon is the ability to grow back after pruning the rootstock in one crop. After harvest, new shoots will grow from the stem in the soil. However, sorghum also has a lower carot- enoid pigment content (xantofil and carotenoid), which is responsible for yolk pigmentation. Until now, the low level of carotenoid pigments in sorghum

was <u>the main</u> limit- ing factor in the ration of laying hens. Sorghum contained low the -carotene (Awika and Rooney, 2004). So that this must be compensated for with other carotene sources such as leaf tops of Indigofera. Indigofera (Indigofera sp.) is a type of legume plant that has been studied in the last 10 years. Indigofera that was cut at the age of 60 days with a cut height of 1.0 m can yield 31.2 tons/ha/year, which is the highest production value compared to yields provided by cutting older or younger plants (Tarigan et al., 2010). The nutritional <u>composition of</u>

Indigofera sp. was 27.97% crude protein, 15.25% crude fiber,

0.22% <u>calcium</u>, and <u>0.18%</u> phosphorus <u>and</u> samples contained 507.6 mg/kg of xantofil and carotenoids (Akba- rillah et al., 2002).

The leaves of legumes <u>can be relied upon as a good</u> carotenoid <u>source</u>

in the ration <u>of</u> laying hens. Laying hens cannot synthesize

pigments but have the abil- ity to transport the pigment to the yolk

of <u>the</u> rations con- sumed. The color or pigment found in <u>eqg yolk</u>

is strongly <u>influenced by the type of</u> pigment contained in the rations consumed (Winarno, 2002). Therefore, the carotenoid pro- file in the yolk reflects the carotenoid profile in the ration fiber by 33% and increase

crude protein by 42% (Wizna et al., 2008). Based on the

information provided <u>above</u>, a <u>study</u> was conducted <u>to</u>

measure <u>the effect of</u> substitution <u>of</u> corn with sorghum and the addition of Indigofera <u>on the performance of laying hens. MATERIALS</u>

AND METHODS Bird, Feed and Laying Hens As many as 200 birds of the ISA Brown strain were used. The birds were 30 weeks old with an average initial weight of  $1625 \pm 44.71$  g. Each replicate consisted of 10 laying hens. The ration used in this study consisted of commercial rations, corn, sorghum, Indigofera leaf flour, palm oil, and premix. At the beginning of the study, each treatment was given Waretha probiotic (Bacillus amyloliquefaciens) at a dose of  $43 \times 1012$  CFU/mL, and administration was done through drinking water. The nutrient (%) and metabolic energy

(kcal/kg) contents of the laying hen feed are shown in Table 1.

Research Procedure The preparation stages of the cage included the

following steps: 1. preparing the feed and drinking containers; 2. cleaning the cages using water, a brush and soap; 3. white- washing the walls, cages, and cage floors; 4. spraying the cages with disinfectant; 5. placing the

chickens in their cages. Feeding trial phase: <u>Feed and</u> drinking <u>water</u>

were given ad libitum. Routine maintenance was carried out for 4 weeks, and in the 4th week, the eggs were collected. After that, the eggs were brought to the examination room for data collection. (Karadas et al., 2006). Experimental Design A completely randomized study design was used

in this Efforts to achieve ration efficiency require several ways so study with four treatments: A. 26% commercial concen- that the protein used can be digested optimally and gives trate + 40% corn + 0% sorghum + 0% Indigofera; B. 23% an influence on productivity, one of which is by adding commercial concentrate + 20% corn + 20% sorghum + 4% probiotics to drinking water. One of the probiotics that Indigofera; C. 22% commercial concentrate + 10% corn + can be used is Waretha probiotics, Waretha Probiotics 30% sorghum + 5% Indigofera; and D. 21% commercial contain Bacillus amyloliquefaciens. Bacillus amyloliquefaciens concentrate + 0% corn + 40% sorghum + 6% Indigofera. have been used as probiotics for poultry (Zurmiati et al., Each treatment was repeated five times. 2017a; Zurmiati et al., 2017c; Tang et al., 2017). B. amy- loliquefaciens produces

enzymes: <u>a-amylase, a-acetolactate</u>, Parameters Measured

Parameter values in the same column showed no significant

 $\underline{differences (P>0.05)}$ . RESULTS Substitution  $\underline{of}$  corn with sorghum and the addition of In- digofera leaf flour <u>on the performance of laying hens.</u>

The effect <u>of</u> the substitution <u>of</u> corn with sorghum and the addition ofIndigofera on the feed consumption, egg mass, feed conversion,

hen-day production, and egg weight of laying hens is shown in

Table 2. At the end of the study, itwas found thatthe use of 40%sorghum added with 6% Indigofera in the ration was able to replace corn by

100% and did not affect (P>0.05) the performance of laying hens.

DISCUSSION <u>The</u> effect <u>of</u> the substitution of corn with sorghum and the addition of Indigofera on the feed consumption, egg mass,

feed conversion, hen-day production, and egg weight of laying hens

is shown in Table 2. At the end of the study, it was found that

the use of 40% sorghum added with 6% Indigofera in the ration was able to replace corn by 100% and did not affect (P>0.05) the performance of laying hens. This is due to the availability of food substances from the

rations <u>consumed by the laying hens</u> in each of <u>the</u>

treatments. Nutritional composition analysis found that sorghum contains metabolic energy, and the digestibility of sorghum is 5% lower than that of corn, but sorghum has a higher crude protein content (NRC, 1994). In ad- dition, Indigofera contains high levels of protein and the nutritional

composition of Indigofera sp. is 27.97% crude protein, 15.25% crude

<u>fiber</u>, 0.22% <u>calcium</u>, and <u>0.18%</u> phosphorus; in addition, sorghum contains 507.6 mg/kg of xantofil and carotenoids (Akbarillah <u>et al.</u>,

2002). <u>The results of this study</u> indicate that <u>the</u> substitution

<u>of</u> corn with sorghum and Indigofera in addition to Bacillus amyloliquefaciens did not interfere with <u>the feed consumption of laying</u>

chickens. <u>This</u> conclusion <u>is</u> supported by <u>the</u> fact that the nutrient content found in sorghum and Indigofera is able to match the contents of corn, and these nutrients function as an energy source. In addition, the addition of Waretha probiotics that are able to produce various types of enzymes aids in the digestion process in the digestive tract of laying hens so that feed is easier to digest. Ba- cillus amyloliquefaciens produces the enzymes <u>a-amylase</u>, <u>a-acetolactate</u>, <u>decarboxylase</u>, <u>β-qlucanase</u>,

hemicellulase, maltogenic amylase, urease, protease, xylanase

(Luizmera, 2005), phytase (Shim et al., 2012), lipase

(Selvamohan <u>et al., 2012)</u> and mannanase (Zurmiati <u>et al.,</u>

2017b). The treatments had no significant effect (P>0.05) on egg

mass. This is because there is no significant effect on hen- day

production	and <u>egg weight. Egg</u>	mass is strongly in- fl	uenced by
hen-day prod	uction and egg weight.	The egg mass value	is

determined by the percentage of egg produc- tion, hen-day

production and the egg weight itself (Kar- tasudjana, 2006), The egg value depends on the percentage of <u>hen-day production and egg weight</u>.

If the egg mass increases, the egg production increases, whereas if the egg mass decreases, the egg production also decreases (Amrul- lah, 2003). The substitution of corn with sorghum by up to 40% and 6% Indigofera addition did not cause a decrease in the of the produced egg weight. The quality of nutrients, espe- cially proteins from Indigofera and the energy

content of sorghum can replace corn energy in the ration. The nutri-

tional <u>content</u> of <u>the ration</u>, especially <u>the</u> energy sources and protein, can affect the feed conversion value (Lokapir- nasari et al., 2011). Factors influencing feed conversion are livestock genetics, age, egg production, energy content in rations, body weight, nutrient content in the feed, air tem- perature, and ration palatability (Campbell et al., 2009). In general, feed conversion is the amount of feed given to produce a certain amount of product (Lokapirnasari et al., 2011). The average of feed conversion of 34-week-old laying hens in this study ranged from 2.51 to

2.48. <u>The results of this study are</u> almost <u>the same as those reported</u>

by Fenita et al. (2010) where the average feed conversion in the

## 32-44 weeks of laying hens ranged from 2. 46 to 2.55. The

treatments had no significant effect (P>0.05) on hen- day production of laying hens. This finding is due to the equal availability of nutrients in the rations of each treat- ment so that there was no significant effect on feed con- sumption, as feed consumption greatly influences hen-day production. The consumed energy and protein in rations is used for maintenance, growth, feather production, and egg production (Bell and Weaver, 2002). Energy and protein consumption that does not meet the standards is a factor that causes low hen-day production. The protein consumed in rations is broken down into amino acids, absorbed by October 2019 | Volume 7 | Issue 10 | Page 832 the body and arranged into tissue proteins and eggs (Sul- toni et al., 2006). The availability of protein rations is very influential on hen-day production because essential amino acid deficiencies can have an impact on the efficient use of protein for tissue formation and cause decreased egg production. The average hen-day production of laying hens of the ISA Brown strain in this study ranged from 83.23 to 84.56%. The results of this study

are similar to those reported by Setiawati et al. (2016), where the average hen-day produc- tion of laying hens of the ISA Brown strain ranged from 86.10 to 89.20%. In Table 2, the egg weight of laying hens ranges from 63.84 to 62.39 g/egg. This is due to the level of feed consumption remaining constant across treatments. As a result, the nu- trients received by chickens such as protein, crude fiber, fat, minerals, vitamins, and other nutrients were relatively the same, so the eqg weights produced among the treatments were similar. Feed consumption is one of the most impor- tant factors affecting egg weight (Saputra et al., 2016). The most important dietary factor that is known to affect the size of eggs is adequate protein and amino acids in the ration. Proteins and amino acids (especially methionine) are food substances that have the greatest role in con- trolling egg size, in addition to genetic factors and poultry body size (Leeson and Summers, 2005). The average egg weights of the laying hens in treatment A, B, C, and D were 63.84, 63.11, 62.32, and 62.39 g/egg, respectively. The results of

## the <u>study were higher than those reported by</u> Pu- lupi <u>et al.</u>

(2014), where the average weight eggs of laying hens ranged from 53.95 to 55.99 g/egg. CONCLUSION The substitution of corn with 40% sorghum, the addition of6% Indigofera leaf flour, and the provision of Waretha probiotics with treatments as high as 43x1012 CFU/mL did not interfere with the performance of laying hens. ACKNOWLEDGMENTS This study was supported by Non-Tax State Revenue funds from Andalas University (002GBI/UN16.6/PPM/PNBP/ Faterna/2018, May 26, 2018). The authors are very grateful to Andalas University, which allowed us to conduct this study. Conflict of interest There is no conflict of interest. authors

contribution Riesi Sriagtula carried out research and helped in making decisions. Ade Djulardi and Ahadiyah Yuniza provided input and criticism for article improvement, Wizna is the corresponding Author, and research organizer and Zurmiati helped with literature studies, data analysis, and helped with correction revisions of Advances in Animal and Veterinary Sciences.
