**II. Experimental design**

This research design used Completely Randomized Design (CRD) with 6 replications which were arranged in a rectangular form for windows. The Treatment factors were A=0 h, B=6 h, C=12 h, D=18 h, E=24 h, F=30 h. The data were analysed using ANOVA and if significantly different were continued with Duncan's New Multiple Range Test (DMRT) at 5% significance level, if the result showed significant difference.

III. RESULT AND DISCUSSION

The Effect of Times Ripening Grated Cassava (*Manihot utilissima*) toward Physical and Chemical Properties of Chips Cassava Produced

Protein Content**Analysing**

Abstract— Research was aimed to know effect of times ripening grated cassava toward physical and chemical properties of chips cassava produced. Ripening is done with various times (0, 6, 12, 18, 24 and 30 h). This Research using design is Completely Randomized Design (CRD) with duplo. Data was analysed statistically with ANOVA and if significantly different were continued with Duncan's New Multiple Range Test (DMRT) at 5% significance level. As a result of this experiment, it was found that, the times of ripening are significantly affect to fat, carbohydrate and fat of chips cassava after fried. Based of this research the best time of ripening is 18h.

Keywords— Time ripening; Physical and chemical; Chips of cassava

water and 95% alcohol to obtain a crude fiber residue [6].

Carbohydrate Content

Carbohydrate content obtained using by different method.

I. INTRODUCTION

Chips of cassava which is commonly called "opak" craker is one of favourite snack especially because its crispy texture. This food is made from mashed cassava which is added with some additional ingredients such as garlic or other seasoning for flavouring agent. After mixing, the dough is steamed and then formed. After that, dried the formed dough and fried.

Cassava (*Manihot utilissima*) is a plant that has carbohydrate as major component which is 34 g. Other component are water (62.50 g), protein (1.20 g), fat (0.30 g), phosphor (40 mg), calcium (33 mg), vitamin C (30 mg), iron (0.70 mg), vitamin B1 (0.06 mg), and the calories (146 kcal) [1]. [2] reported that raw cassava consist of water content (60%), starch (35%), fiber (2.5%), protein (1%), fat (0.5 %), and ash content (1%).

According to interview report with chips of cassava manufacture at Lareh Sago Halaban, Lima Puluh Kota, West Sumatera-Indonesia, they are usually ripent (ferment) the cassava grater before formed it. It is caused, this process more efficient, beside that they are assumed that the dough is bigger which caused amount of chips cassava is higher. It might be because of microbe activities during fermentation. Cassava grater obtains flavour after fermentation. Microorganism that give biggest influence

during fermentation on cassava grater is amylolytic microorganism which needs high carbohydrate content for growing up. This microbe will obtain amylase enzyme that can hidrolyze starch to be simple component.

Microbe that obtains amylase enzyme commonly grouped as mold which it can hydrolyze starch to be its monomer. One of amylase enzyme that able to hydrolyze starch to glucose is glucoamylase. Other amylase such as alfa amylase or beta amylase that can obtain maltose and maltoriosa [3]. According to that information, this research is aimed to determine length of ripening (fermentation) that is affected to the physical and chemical chips of cassava characteristic.

II. MATERIAL AND METHODE

A. Material

Samples were obtainable from chips of cassava manufacture where is located at Kecamatan Lareh Sago Halaban Kabupaten Lima Puluh Kota, West Sumatera-Indonesia. Samples were fresh cassava grater which were taken using sterilized spoon.

B. Fermentation Process

Fermentation process has been done in facultative anaerobic circumstances. Length of fermentation has been determined according to research treatment. To obtain an appropriate length of fermentation, fermentation process has been started from the longest time.

C. Analysis

Moisture Content (Gravimetry)

Approximately 2 gram of samples on the porcelain cups were dried in oven with the temperature of 100-105°C until a constant weight reached. Subsequently it were stabilized in desiccator. Water content was calculated on wet basis [4].

Ash Content

Porcelain cups were dried on the furnace which temperature degree was 110°C for 1 hour. Then, the cups were be chilled on desiccator. 2 gram of samples on porcelain cups were charred on the hot plate until no more smoke released. After that, samples were charred using furnace which temperature around 500°C-600°C for 2 hours [5].

Protein Content

Analysis of protein content by kjedal methode [4].

Fat Content (Soxhlet)

Analysis of fat content by soxhlet methode. [5]

Crude Fiber

Crude fiber content analysis was conducted by heat treatment of acids and bases method. The principle of this analysis is washing the sample with acids, bases, boiled water and 95% alcohol to obtain a crude fiber residue [6].

Carbohydrate Content

Carbohydrate contentwas obtained using by different method.

Oil Absorbtion of Cassava Craker

Oil absorption was measured by counting differences of oil content after used and before used [5].

Yield

Yield of cassava grater was measured by dividing weigh of cassava grater before ripening and the weigh after ripening, then multiplied 100 %.

Degree of Cassava Cracker Development

Samples were measured using a micrometer (vernier caliper 0-150 mm x 0.05, Shanghai-China) at five different places. An average value was calculated in mm. [7]

Total Plate Count

Total plate count was determine using agar method. Dilution has been prepared until 10^{-6} . After that, cultivation has been done using casting method. Incubation has been done for 24 hours. After that, colony counted used SPC method [8].

D. Experimental design

This research design used Complete Random Design (CRD) with 3 replications which used SPSS 16.0 software for windows. The Treatments were A= 0 H (control), B= 6 H, C= 12 H, D= 18 H, E= 24 H and F= 30 H. Datas were analysed using ANOVA and continued using Duncan's New Multiple Range Test (DNMRT) at 5% significant level, if the result showed significantly difference

III. RESULT AND DISCUSSION

A. Chemical Properties

Fermentation is a process to decompose an organic substances using microorganism activity (system biology) and enzymes activity that can generate energy. [9] reported, during fermentation process, the microorganisms use organic matter as a substrate to generate energy, to build cell components, and to produce metabolites products. Furthermore, due to microorganisms activities, fermented material will encounter some biochemical changes. During fermentation process of grated cassava, starch is overhauled into simpler components (glucose), alcohols, organic acids, carbondioxide and water. [10], during fermentation process of cassava starch, the starch will be split into alcohols, acids and water.

Fermentation process of grated cassava occurs spontaneously which microorganism is obtained from grated cassava. Starch is decomposed by microorganisms in appropriate environement. [11], microorganisms needs nutrients for growing up, then the microorganisms has a wide variety of enzymes to decompose components of food into simpler compounds. Those microorganisms grouped as amylase enzyme producer is called amyloytic microorganisms. It's suitable with the main components of cassava that is carbohydrate.

Microorganism that grows on the materials containing carbohydrates is faster to grow compared to microorganism that grows on the material containing more protein or fat. [9], [11] and [12] reported, at the beginning microorganisms will decompose carbohydrate, then followed protein decomposition and fat decomposition at the last. There is also some steps to decompose carbohydrate by microorganism, first, carbohydrate will be decomposed becoming sugar, then alcohol, and after that becoming acid. So according to statistic result, lenght of fermentation process significantly affected to the carbohydrate content. Carbohydrate content was increasing while longer fermentation process, this process caused by microorganism activities. Graphic of carbohydrate content is showed on figure 1.

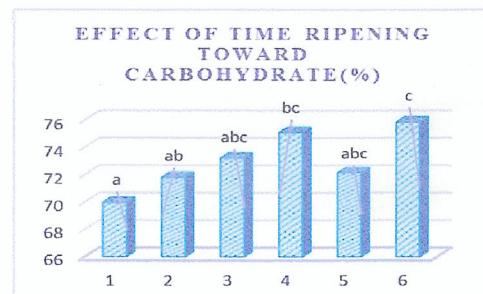

Figure 1. Grafic of Carbohydrate Content

Along with that, longer fermentation process was affected to protein and fat content decreased due to decomposition of protein and fat hydrolysis which were caused by microorganism activities. [13] reported, some food processing (in this case fermenting, steaming and drying) cause decomposition of fat content. Fat content on fermented grated cassava and placebo had significant differences indicated fat hydrolysis has been occurred during fermentation process. [11] reported, protein decomposition by microorganisms through an enzyme, protein is decomposed into simpler compounds. Furthermore, the fat will be hydrolyzed into fatty acids and glycerol. Grafic of fat content is showed on figure 2.

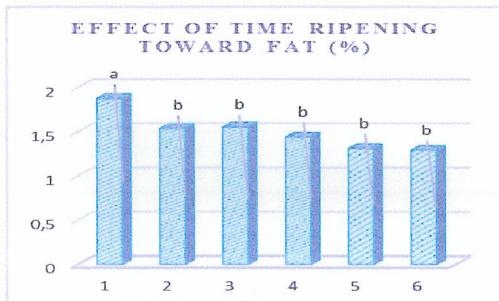

Figure 2. Grafic of Fat Content

Crude fiber content also tend to increase due to fermentation process, eventough, statistically length of fermentation was not significantly affected to the crude fiber content. According to [14] crude fiber content on fermented cassava flour (Mocaf) is higher compared with original cassava flour. Crude fiber is the residue of foodstuffs composed which consist of cellulose and lignin after acid and alkali treated [6]. Furthermore [15] declare, cellulose is bound by lignin which has higher molecular weight, so it only can be decomposed by certain microorganism which also capable to produce only certain

enzyme, that microorganism is called cellulolytic microorganisms.

Water content in cassava flour was decreasing while longer fermentation process (up to 18 hours of fermentation process). However, statistically, length of fermentation process was not significantly affected to water content on cassava cracker. Basically, the length of fermentation process will increase the moisture content in the material (before drying) because increasing of starch decomposed which further decomposition process to be alcohols, acids and water. [10] reported, longer the fermentation process will increase water content on cassava which starch will be more decomposed which is also affected to alcohol, acid, and water decomposition.

However, during steaming and drying were occurred expenditure or partial removal of water from crackers. Evaporated water was free water contained in the material. Meanwhile decomposition process was undertaken by microorganisms. Those process cause the cell which was opened and the water was leaked out. So that more decomposition occurred on material during fermentation will affect to evaporation process during steaming and drying. [16] increasing of decomposition material will increase amount of evaporated water during heating. [9] said, the drying process is a process of evaporation which mostly to water content on the materials through heat energy.

Length of fermentation was not significantly affected to ash content on cassava chips produced, although the tendency decreasing of ash content was occurred while longer fermentation process. Ash contained on crackers indicates mineral content (calcium, phosphorus and iron) in cassava. According [17], cassava contains 73.7 mg / 100 minerals g. Chemical properties of cassava chips after ripening show on table 1.

TABLE I
CHEMICAL PROPERTIES OF CHIPS CASSAVA

Treatment	Carbohydrate (%)	Soluble crude (%)	Protein (%)	Fat (%)	Moisture content (%)	Ash content (%)
0 H	69,958 a ± 5,37	2,717 ± 0,09	4,646 ± 0,14	1,874 a ± 0,02	4,819 ± 0,009	0,251 ± 6,15
6 H	71,789 ab ± 3,61	2,895 ± 0,004	4,044 ± 0,07	1,536 b ± 0,002	4,484 ± 0,32	0,247 ± 1,04
12 H	73,199 abc ± 3,05	2,955 ± 0,007	4,059 ± 0,11	1,552 b ± 0,01	4,240 ± 0,45	0,244 ± 0,38
18 H	75,078 bc ± 0,15	2,979 ± 0,002	3,715 ± 0,0001	1,438 b ± 0,004	3,725 ± 0,25	0,241 ± 0,11
24 H	72,140 abc ± 0,39	3,075 ± 0,04	4,129 ± 0,28	1,311 b ± 0,01	5,096 ± 0,12	0,322 ± 0,14
30 H	75,828 c ± 0,19	3,021 ± 0,029	4,072 ± 0,003	1,290 b ± 0,008	4,265 ± 0,01	0,243 ± 0,27

B. Physical Properties

The yields were ranged between 47, 274% s / d 54, 634, longer fermenrtation process was tend to affect toward increasing of yields, but statiscally, it was not significantly affected to the yields. That was occurred because of microorganism activities, starch was more decamped which was affected to gelatinization process during This is because mikroorganism activity during the curing process, the more starch overhauled, gelatinization process that occurs during the kneading and steaming. That process was suitable according to [18] statement, during fermentation process of cassava flour, microorganisms will perforate the starch granules which make starch granule more cohesive. So that process was affected to the chips of cassava texture.

Degree of cassava cracker development was also affected caused by microorganisms. [19] state that, it is affected by gelatinization process. Longer fermentation process increased dgree of cassava cracker development, but statistically the result was not significantly affected. During gelatinization process, the starch granules will be perforated which was affected to greater degree of chips cassava development compared with the undecomposed starch. Degree of development was inversely proportional to the fat content. Higher fat content will affect to lower degree of cassava cracker development. The presence of fat in the dough crackers can disrupt the process of gelatinization because layer of fat on the surface of granules which causes water penetration disrupted. Physical properties of cassava cracker are showed on table 2.

TABLE III
PHYSICAL PROPERTIES

Treatment	Yield (%)	Degree of Chips Cassava Development (%)
0 H	47,274 ± 1,38	34,095 ± 0,45
6 H	50,789 ± 3,05	41,158 ± 2,18
12 H	52,445 ± 1,48	42,058 ± 0,10
18 H	54,634 ± 0,62	49,169 ± 1,67
24 H	53,023 ± 1,77	47,626 ± 10,33
30 H	51,792 ± 0,24	44,707 ± 0,09

Fat content on fried crackers tends to decrease when the longer fermentation process. Increasing of fat content on fried crackers caused by oil absorption during frying process. Oil absorption is differences content of fat before and after frying which also affected by gelatinization. Gelatinization process will affect the volume [20]. Similar with fat content on chips of cassava before frying, length of fermentation was also significantly affected to fat content on fried. Oil absorption of cassava crackers are showed on table 3 and the graphic is showed on figure 3.

TABLE III
FAT AND OIL ABSORPTION OF CASSAVA CHIPS AFTER FRIED

Treatment	Fat of Chips Cassava(%)	Oil Absorption After Fried (%)
0 H	26,806 ± a 0,75	24,932 ± 1,07
6 H	23,993 ± a 0,36	22,457 ± 0,41
12 H	23,666 ± ab 2,54	22,114 ± 2,93
18 H	23,044 ± ab 3,13	21,605 ± 2,90
24 H	20,260 ± ab 2,85	18,949 ± 3,26
30 H	20,044 ± b 7,51	18,754 ± 7,01

EFFECT OF TIME RIPENING TOWARD FAT AFTER FRYING(%)

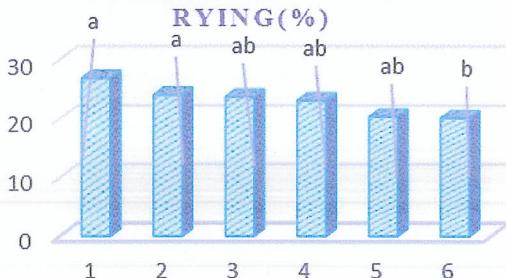

Figure 3. Grafic of Fat Chips of Cassava After Frying

C. Microorganism Analysis

Table 4. shows total plate count on cassava cracker. Data of total plate count on unfermented grated cassava was initial number of microorganisms that was existed in the grated cassava. The initial microorganism can be carried from processing or the raw material itself. Total plate count tends to increase up to 18 hours of fermentation process, which was indicated fermentation process affected to development of microorganisms. Microorganisms that grow are amylolytic group characterized by a milky white colonies surrounded by yellow areas (showed on figure 4). However ALT decreased during fermentation when it had been 24 hours, indicated the development of microorganisms had already on the phase statisiner. [20] state that, the growth of microorganism is consist of four phases , such as ; the lag

phase, log phase, statisiner phase , and decreased phase. Then total plate count increased at 30 hours fermentation indicated there was possible growth of contaminants

TABLE IVII
TOTAL PLATE COUNT

Treatment	Total Plate Count (cfu/g)
0 H	7,3 * 10 ³
6 H	1,1 * 10 ⁴
12 H	1,5 * 10 ⁴
18 H	1,6 * 10 ⁴
24 H	1,4 * 10 ⁴
30 H	2,3 * 10 ⁴

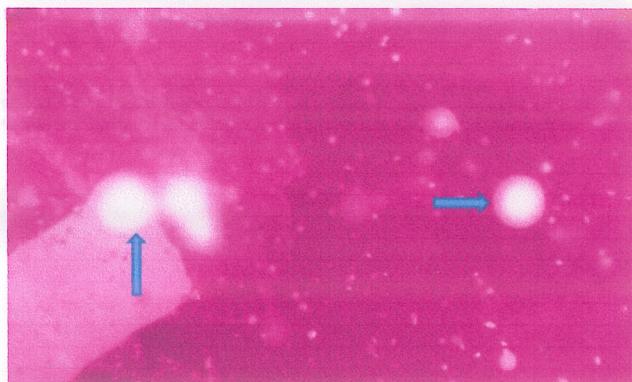

Figure 4. Amylolytic Colony on Agar Media

IV. CONCLUSION

Based on research length of fermentation process of grated cassava significantly affected to the fat content, carbohydrate content, and fat content after after fying. The best treatment of fermentation was 18 hours. The characteristic of cassava cracker was: carbohydrate 75.078%, crude fiber 2,979%, protein 3.715%, fat 1.438%, moisture content 13.725% and the ask content 6.041%. for physical properties were the yield of 54.634%, the degree of cassava cracker development 49.169%, fat content after frying 23, 044%, and oil absorption 21.605%. For total plate count was 1.6×10^4 cfu / g.

ACKNOWLEDGMENT

The author expressed a great acknowledge for financial support from DIPA of Agriculture Technology, Andalas University.

Nong Lam University is the proud host of the SAFE 2015 conference. The conference will culminate in our 60th anniversary celebration on the 19th of November, representing six decades of achievement in research and teaching. Established in 1955 as the BLAO National College of Agriculture, NLU has a rich legacy of education, extension dissemination, and innovation in science and technology. We have robust research facilities, with a 118-hectare campus and dozens of internationally trained scholars. With the SAFE conferences' international distinguished guests here in Ho Chi Minh City, Nong Lam's 60th anniversary will be even more significant.

The Effect of Times Ripening Grater Cassava (*Manihotutilissima*) toward Physical and Chemical Properties of Crackers Produced

Wenny Surya Murtius

Department of Product Agricultural Technology Faculty of Agricultural Technology Andalas University, Padang, Indonesia. corresponding author : wenny.murtius@gmail.com

Abstract: This research was aimed to know effect of times ripening grated cassava toward physical and chemical properties of crackers produced. Ripening is done with various times (0 , 6, 12, 18, 24 and 30 h). This Research using design is Completely Randomized Design (CRD) with duplo. Data was analysed statistically with ANOVA and if significantly different were continued with Duncan's New Multiple Range Test (DMRT) at 5% significance level. As a result of this experiment, it was found that, the times of ripening are significantly affect to fat, carbohydrate, yield, degree of crackers development and fat of crackers after fried. Based of this research the best time of ripening 18h.

Keywords : crackers, cassava, *Manihotutilissima*, crackers produced

Development of Green Banana (*Musa paradisiaca*) as Potential Packaging Films

Nur Hanani, Z. A., Abdullah, S.

Department of Food Technology, Faculty of Food Science and Technology, Universiti Putra Malaysia, 43400 UPM, Serdang, Selangor, Malaysia
corresponding author : Hanani@upm.edu.my

Abstract : The aim of this study was to develop biodegradable packaging films based on unripe green banana (*Musa paradisiaca* L.) with different concentration of plasticizers; glycerol, polyethylene glycol (PEG) and sorbitol. Banana films were produced by using casting method and physical properties of these films were determined. Banana films with 10% of PEG showed the lowest water solubility followed by films with glycerol and sorbitol. Banana films with 40% PEG showed the lowest water vapour permeability (WVP) whereas films with 30% glycerol possessed the higher values of mechanical properties compared to films with PEG and sorbitol. Types of plasticizers do not influence the thickness of the films. In general, type of plasticizers used in banana films not influenced the mechanical properties of banana films. However, increasing the plasticizers concentrations had increased the solubility values.

Keywords : Banana; Biodegradable films; Packaging

Keywords : chitosan; gelatin formulation; edible film; food casing; instant noodles
